**Abstract.** In this paper we extend our correlation functions to the open/closed case. This gives rise to actions of an open/closed version of the Sullivan PROP as well as an action of the relevant moduli space. There are several unexpected structures and conditions that arise in this extension which are forced upon us by considering the open sector. For string topology type operations, one cannot just consider graphs, but has to take punctures into account and one has to restrict the underlying Frobenius algebras. In the moduli space, one first has to pass to a smaller moduli space which is closed under open/closed duality and then consider covers in order to account for the punctures.

*Key words:* string topology; Hochschild complex; double sided bar complex; foliations; open/closed field theory; moduli spaces; clusters of points

*2010 Mathematics Subject Classification:* 55P48; 81T30; 57R30; 16E40; 55P50

## 1 Introduction

There has been a lot of interest in studying open/closed theories from physics and mathematics. In physics this goes back to boundary CFTs and D-branes with an extensive literature. In mathematics motivation come from open/closed string topology, Gromov–Witten invariants and TQFT again with a virtual onslaught of ideas. Sources relevant to our constructions are [3, 18, 19, 20]. In this spirit, there have been many interesting forays into the subject of open/closed operations [21, 4, 1, 5, 2].

Our point of view comes from the geometry provided in [11, 7] and the operations on Hochschild complexes defined in [8] via correlations functions. In this paper, we extend these correlation functions to the open/closed case. This leads to a dg-action of a Sullivan-type PROP yielding string topology type operations and a cell level moduli space action on Hochschild complexes. There are several surprising details and conditions which to our knowledge have not been fully discussed previously. These obstacles make the passage from the closed case to the open/closed case far from being evident.

The first is that – unlike the closed case – in the open/closed case, the role of punctures cannot be suppressed, as they can arise as the result of an open gluing. These punctures contribute new factors to the correlators. Another consequence of the presence of punctures is that in the moduli space case the underlying ribbon graph needs extra decorations marking possible punctures and one cannot define the string topology type operations just by looking at open/closed graphs of Sullivan type. One has to know the puncture structure inside the complementary regions as well.

---

\*This paper is a contribution to the Proceedings of the XVIIIth International Colloquium on Integrable Systems and Quantum Symmetries (June 18–20, 2009, Prague, Czech Republic). The full collection is available at <http://www.emis.de/journals/SIGMA/ISQS2009.html>

Secondly we need a compatibility equation for the dg-PROP to operate, which is satisfied if the coefficient modules of the Hochschild complexes have a geometric origin. A further unexpected detail is that the moduli space is not the first moduli space one would choose. For each moduli space one has to pick out a subspace that satisfies open/closed duality and then consider covers or rather spaces which are stratified by covers of the usual moduli spaces. These are brane labelled open/closed moduli spaces  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s,\beta}$  of bordered surfaces with punctures on the boundary and clusters of marked points on the interior.

The main results are

**Theorem 1.** *There is an open/closed colored  $\beta$  brane labelled c/o dg-PROP cell model of the open/closed colored brane labelled topological quasi PROP (see Appendix A.7)  $\widetilde{\mathcal{S}}ull^{c/o}$  which acts in a brane labelled open/closed colored dg-PROP fashion on the brane labelled Hochschild complexes for a  $\beta$ -Frobenius algebra which satisfies the Euler condition (E); see Definition 4.5.*

This theorem defines open/closed string topology type actions for compact manifolds that are simply connected.

**Theorem 2.** *There is an operadic cell model associated to the  $\beta$ -brane labelled open/closed moduli spaces  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s,\beta}$  which acts on  $\beta$ -labelled Hochschild co-chains via operadic correlation functions with values in a  $\beta$ -labelled Hom operad.*

The actions in both cases are made possible by a discrete version of the c/o action.

**Theorem 3.** *For a basic  $\mathcal{B}$ -Frobenius algebra the c/o structure of discretely weighted arc-graphs acts on the collection of complexes  $B(\beta)$  and the isomorphic Hochschild complexes via the correlation functions  $Y$  defined by equations (4) and (5).*

The restriction basic  $\mathcal{B}$ -Frobenius algebras is simply of expository nature. We can deal with general systems of  $\mathcal{B}$ -Frobenius algebras. For this we would introduce a new propagator formalism which we will do elsewhere as not to put even more technical structures into this exposition.

We begin by reviewing the relevant structures from [11] in Section 2. We then go on to construct the relevant spaces which carry the topological structures. The first of these is taken from [11] and is concerned with graphs on windowed surfaces. We define a generalization and a restriction of this structure. The restriction is the space that yields moduli spaces of curves with marked points and tangent vectors, while the extension is used to define the open/closed Sullivan PROP. We also briefly discuss the moduli space  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s,\beta}$  which provides the chain models for the moduli space action. In all these cases, we associate a chain complex to these spaces where each basis element, or cell, is indexed by a graph of arcs on the given windowed surface.

In Section 3, we review the open/closed gluing operations in the geometrical setting. The algebraic counterpart is given by brane labelled bar complexes of brane labelled systems of Frobenius algebras which we introduce in Section 4.

The correlators in the discrete case are given in Section 5. This is the technical heart of the paper and yields Theorem 3. Given a graph on a windowed surface which has a discrete weighting on its edges or arc there is a universal formula for a correlation function. This extends our formula of [8] to the open/closed case. In Section 6 we give the details of the PROPic version of the actions, which lead to open/closed string topology operations. The section culminates in Theorem 1. In Section 7 we give the details on our moduli space actions and the proof of Theorem 2. We close the main part of the paper with an outlook. In an appendix, we recall the rather technical definition of a brane labelled c/o structure and the other operadic and PROPic structures we use.

## 2 Review of the KP-model for open/closed strings

We recall the main features of the KP-model for open/closed string interactions via foliations [11]. The interactions are given by surfaces with boundary and punctures together with a foliation. There are marked points on the boundary (at least one per boundary) and possibly also marked points in the surface. The part of the boundary between two marked points is called a window.

The foliation is thought of as being transverse to the propagating string and as keeping track of splitting and recombining of pieces of string. The foliation and its partial transverse measure are encoded in a graph of weighted arcs. Furthermore there is the data of a brane labelling which keeps track of the branes that the strings might end on.

Given two windows, either on two disjoint surfaces or on the same surface, we can glue them and the foliations together if their weights agree on these windows. In [11] we showed that this gluing gives rise to an  $c/o$  structure on the topological level and induces chain level operations, which descend to a bi-modular operad on the homology level.

More technically, the setup is as follows:

### 2.1 Arc graphs in brane labelled windowed surfaces

A *windowed surface*  $F = F_g^s(\delta_1, \dots, \delta_r)$  is a smooth oriented surface of genus  $g \geq 0$  with  $s \geq 0$  punctures and  $r \geq 1$  boundary components together with the specification of a non-empty finite subset  $\delta_i$  of each boundary component, for  $i = 1, \dots, r$ , and we let  $\delta = \delta_1 \cup \dots \cup \delta_r$  denote the set of all distinguished points in the boundary  $\partial F$  of  $F$  and let  $\sigma$  denote the set of all punctures. The set of components of  $\partial F - \delta$  is called the set  $W$  of *windows*.

Furthermore one needs to specify a brane labelling  $\beta$ . For this we first fix a set  $\mathcal{B}$  of basic brane labels and denote by  $\mathcal{P}(\mathcal{B})$  power set. Notice that  $\emptyset \in \mathcal{P}(\mathcal{B})$ , this will encode the closed sector. The elements of  $\mathcal{P}(\mathcal{B})$  of cardinality bigger than one should be thought of as intersecting branes. These give room for extra data, but it is possible to set all the contributions for these “higher intersection” branes to zero in a given model.

A *brane-labeling* on a windowed surface  $F$  is a function

$$\beta : \delta \amalg \sigma \rightarrow \mathcal{P}(\mathcal{B}),$$

where  $\amalg$  denotes the disjoint union, so that if  $\beta(p) = \emptyset$  for some  $p \in \delta$ , then  $p$  is the unique point of  $\delta$  in its component of  $\partial F$ . A brane-labeling may take the value  $\emptyset$  at a puncture.

A window  $w \in W$  on a windowed surface  $F$  brane-labeled by  $\beta$  is called *closed* if the endpoints of  $w$  coincide at the point  $p \in \delta$  and  $\beta(p) = \emptyset$ ; otherwise, the window  $w$  is called *open*. Each window defines a pair of brane labels  $\beta(w)$  which is the pair  $(S, T)$  of the brane labels of the beginning and end of the window (these may coincide).

#### 2.1.1 Arc families

We define the sets

$$\delta(\beta) = \{p \in \delta : \beta(p) \neq \emptyset\}, \quad \sigma(\beta) = \{p \in \sigma : \beta(p) \neq \emptyset\}.$$

Define a  $\beta$ -arc  $a$  in  $F$  to be an arc properly embedded in  $F$  with its endpoints in  $W$  so that  $a$  is not homotopic, fixing its endpoints, to  $\partial F - \delta(\beta)$ . For example, given a distinguished point  $p \in \partial F$ , consider the arc lying in a small neighborhood that simply connects one side of  $p$  to another in  $F$ ;  $a$  is a  $\beta$ -arc if and only if  $\beta(p) \neq \emptyset$ . We will call such an arc a *small arc* around  $p$ .

Two  $\beta$ -arcs are *parallel* if they are homotopic rel  $\delta$ , and a  $\beta$ -arc family is the homotopy class rel  $\delta$  of a collection of  $\beta$ -arcs, no two of which are parallel. Notice that we take homotopies rel  $\delta$  rather than rel  $\delta(\beta)$ .

Given a positively weighted arc family in  $F$ , let us furthermore say that a window  $w \in W$  is *active* if there is an arc in the family with an endpoint in  $w$ , and otherwise the window is *inactive*.

### 2.1.2 The mapping class group and arc graphs

The (pure) mapping class group  $MC(F)$  of  $F$  is the group of orientation-preserving homeomorphisms of  $F$  pointwise fixing  $\delta \cup \sigma$  modulo homotopies pointwise fixing  $\delta \cup \sigma$ .

$MC(F)$  acts naturally on the set of  $\beta$ -arc families. An *arc graph* is an equivalence graph under this action.

## 2.2 Arc spaces, moduli spaces and the open/closed Sullivan PROP

### 2.2.1 The Arc spaces

A *weighting* on an arc family is the assignment of a positive real number to each of its components. A weighting naturally passes to the arc graph. A weighting is called *discrete* if it takes values in  $\mathbb{N}$ .

Let  $\text{Arc}'(F, \beta)$  denote the geometric realization of the partially ordered set of all  $\beta$ -arc families in  $F$ .  $\text{Arc}'(F, \beta)$  is described as the set of all projective positively weighted  $\beta$ -arc families in  $F$  with the natural topology. (See for instance [12] or [15] for further detail.)

$MC(F)$  again acts naturally on  $\text{Arc}'(F, \beta)$ . The *arc complex* is defined to be the quotient under this action

$$\text{Arc}(F, \beta) = \text{Arc}'(F, \beta) / MC(F).$$

We shall also consider the corresponding deprojectivized versions:  $\widetilde{\text{Arc}}'(F, \beta) \approx \text{Arc}'(F, \beta) \times \mathbb{R}_{>0}$  is the space of all positively weighted arc families in  $F$  with the natural topology, and

$$\widetilde{\text{Arc}}(F, \beta) = \widetilde{\text{Arc}}'(F, \beta) / MC(F) \approx \text{Arc}(F, \beta) \times \mathbb{R}_{>0}.$$

For any windowed surface  $F$ , define

$$\widetilde{\text{Arc}}(F) = \bigsqcup \widetilde{\text{Arc}}(F, \beta),$$

where the disjoint union is over all brane-labellings on  $F$ .

$$\widetilde{\text{Arc}}(n, m) = \bigsqcup \left\{ \alpha \in \widetilde{\text{Arc}}(F) : \begin{array}{l} \alpha \text{ has } n \text{ closed and } m \text{ open active} \\ \text{windows and no inactive windows} \end{array} \right\},$$

where the disjoint union is over all orientation-preserving homeomorphism classes of windowed surfaces.

## 2.3 The open/closed Sullivan spaces

As proved in [11], the spaces  $\widetilde{\text{Arc}}(n, m)$  form an c/o structure, see the appendix for the complete definition. We will now construct a suitable PROP to capture string topology type operations. First, we have to add additional data to the surface  $(F, \beta)$ , which is a partitioning i/o :=  $\{W_{\text{in}}, W_{\text{out}}\}$  of all of the windows of  $F$  into “in” and “out” windows. A  $\beta$ -arc family (or arc graph) on such a surface is called of *Sullivan type* if

1. arcs only run from “in” windows to “out” windows,
2. all *in* windows are active.

We set  $\mathcal{Sull}^{c/o'}(F, \beta, i/o)$  the geometric realization of the partially ordered set of all  $\beta$ -arc families of Sullivan type. And let  $\mathcal{Sull}^{c/o}(F, \beta, i/o)$  be the quotient under the action of  $MC(F)$ . As above, we also consider the deprojectivized versions  $\widetilde{\mathcal{Sull}}^{c/o}(F, \beta, i/o)$

$$\widetilde{\mathcal{Sull}}^{c/o}(F) = \bigsqcup \widetilde{\mathcal{Sull}}^{c/o}(F, \beta, i/o),$$

where the disjoint union is over all brane-labellings on  $F$  and partitions  $i/o$ .

$$\widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2) = \bigsqcup \left\{ \alpha \in \mathcal{Sull}^{c/o}(F) : \begin{array}{l} \alpha \text{ has } n = n_1 + n_2 \text{ closed and } m = m_1 + m_2 \text{ open} \\ \text{windows with } n_1 \text{ and } m_1 \text{ active closed resp. open "in"} \\ \text{windows and } n_2, m_2 \text{ closed resp. open "out" windows} \end{array} \right\},$$

where the disjoint union is over all orientation-preserving homeomorphism classes of windowed surfaces.

Notice that  $\widetilde{\mathcal{Sull}}^{c/o}(n, m)$  is also graded by the number  $k$  of inactive “out” windows – by definition all “in” windows are active.

## 2.4 Moduli space

The spaces of  $\beta$  arc families contains a moduli space. We call an arc family or graph *quasi-filling*, if all complementary regions are polygons or once punctured polygons.

The weighted quasi-filling graphs form a subspace of each  $\text{Arc}(F, \beta)$  which is homeomorphic to the moduli spaces  $\mathcal{M}_{g, t_1, \dots, t_n}^s$  of genus  $g$  surfaces with  $n + s$  marked points, where for the first  $n$  marked points  $t_i \geq 1$  tangent vectors at the  $i$ th marked point are specified. This is independent of  $\beta$  since the small arcs only thicken the moduli spaces by a factor of  $\mathbb{R}_{>0}$ . This fact is straightforward using the dual graph and Strebel differentials [17].

### 2.4.1 Open/closed duality moduli space of open/closed brane labelled surfaces with marked point clusters

The moduli space  $\mathcal{M}_{g, t_1, \dots, t_n}^s$  is actually too small and too big for its cell model to act, as we will discuss below. It is too big in the sense that there are gluings which when allowing open windows on boundaries unexpectedly take us out of moduli space on the chain level; see Figs. 7 and 8. There is however a subspace of this space given by the arc families that are in general position with respect to the open/closed duality (see Fig. 9) which solves this problem. The other problem that arises which is unique to the open sector is that unlike in [7, 8] we cannot restrict to the case of no punctures;  $s = 0$ . But gluing with internal punctures is again not stable in the moduli space case. This problem is overcome by introducing clusters of brane labelled points. The resulting space is the open/closed duality moduli space of open/closed brane labelled surfaces with marked point clusters  ${}^{c/o}\mathcal{M}_{g, \delta_1, \dots, \delta_n}^{s, \beta}$ . The details are given in Section 7 below.

## 3 Geometric c/o structures

In [11] we axiomatized a structure of spaces that allow four different types of gluing: i.e. either open or closed and either self or non-self gluings together with a coloring of the open gluings by brane labels  $\beta$ . In the above case the gluing is on two windows, which are either both open or closed and either belong to the same (self gluing) or disjoint surfaces (non-self gluing). The coloring is by the brane labels. The color of a window is the pair of brane labels of its end

points. When we glue  $\beta$  arc families, we glue the surfaces and glue the arc families as foliations. We will now review this process according to [11].

### 3.1 The gluing underlying the topological c/o structure

If  $\alpha \in \widetilde{\text{Arc}}(n, m)$ , then define the  $\alpha$ -weight  $\alpha(w)$  of an active window  $w$  to be the sum of the weights of arcs in  $\alpha$  with endpoints in  $w$ , where we count with multiplicity (so if an arc in  $\alpha$  has both endpoints in  $w$ , then the weight of this arc contributes twice to the weight of  $w$ ).

Suppose we have a pair of arc families  $\alpha_1, \alpha_2$  in respective windowed surfaces  $F_1, F_2$  and a pair of active windows  $w_1$  in  $F_1$  and  $w_2$  in  $F_2$ , so that the  $\alpha_1$ -weight of  $w_1$  agrees with the  $\alpha_2$ -weight of  $w_2$ . Since  $F_1, F_2$  are oriented surfaces, so are the windows  $w_1, w_2$  oriented. In each operation, we identify windows reversing orientation, and we identify certain distinguished points.

To define the open and closed gluing ( $F_1 \neq F_2$ ) and self-gluing ( $F_1 = F_2$ ) of  $\alpha_1, \alpha_2$  along the windows  $w_1, w_2$ , we identify windows and distinguished points in the natural way and combine foliations.

A crucial difference between the closed and open string operations is that in the closed case, the points are thought of as marked, which in the open case the points behave like punctures. This means that in the closed case, we replace the distinguished point by simply forgetting that it was distinguished. This way no puncture is created. In the open case the distinguished points always give rise to other distinguished points or perhaps punctures. In any case whenever distinguished points are identified, one takes the union of brane labels (the intersection of branes) at the new resulting distinguished point or puncture.

#### 3.1.1 Closed gluing and self-gluing

Identify the two corresponding boundary components of  $F_1$  and  $F_2$ , identifying also the distinguished points on them *and then including this point in the resulting surface*  $F_3$ .  $F_3$  inherits a brane-labeling from those on  $F_1, F_2$  in the natural way. We furthermore glue  $\alpha_1$  and  $\alpha_2$  together in the natural way, where the two collections of foliated rectangles in  $F_1$  and  $F_2$  which meet  $w_1$  and  $w_2$  have the same total width by hypothesis and therefore glue together naturally to provide a measured foliation  $\mathcal{F}$  of a closed subsurface of  $F_3$ .

#### 3.1.2 Open gluing

The surfaces  $F_1$  and  $F_2$  are distinct, and we identify  $w_1$  to  $w_2$  to produce  $F_3$ . There are cases depending upon whether the closure of  $w_1$  and  $w_2$  is an interval or a circle. The salient cases are illustrated in Fig. 1, b–d. In each case, distinguished points on the boundary in  $F_1$  and  $F_2$  are identified to produce a new distinguished boundary point in  $F_3$ , and the brane labels are combined, as is also illustrated. As before, since the  $\alpha_1$ -weight on  $w_1$  agrees with the  $\alpha_2$ -weight on  $w_2$ , the foliated rectangles again combine to provide a measured foliation  $\mathcal{F}$  of a closed subsurface of  $F_3$ .

**Open self-gluing.** There are again cases depending upon whether the closure of  $w_1$  or  $w_2$  is a circle or an interval, but there is a further case as well when the two intervals lie in a common boundary component and are consecutive. Other than this last case, the construction is identical to those illustrated in Fig. 1, b–d. In case the two windows are consecutive along a common boundary component, again they are identified so as to produce a surface  $F_3$  with a puncture resulting from their common endpoint as in Fig. 1, e–f, where the puncture is brane-labeled by the label of this point, and the foliated rectangles combine to provide a measured foliation  $\mathcal{F}$  of a closed subsurface of  $F_3$ .

**Figure 1.** The different cases of gluing.

At this stage, we have only constructed a measured foliation  $\mathcal{F}$  of a closed subsurface of  $F_3$ , and indeed,  $\mathcal{F}$  will typically not be a weighted arc family, but the sub-foliation  $\mathcal{F}'$  comprised of leaves that meet  $\partial F$  corresponds to a weighted arc family  $\alpha_3$  in  $F_3$ . Notice that the  $\alpha_3$ -weight of any window uninvolved in the operation agrees with its  $\alpha_1$ - or  $\alpha_2$ -weight.

The assignment of  $\alpha_3$  in  $F_3$  to  $\alpha_i$  in  $F_i$ , for  $i = 1, 2$  completes the definition of the various operations. Associativity and equivariance for bijections are immediate, and so we have our first non-trivial example of a c/o structure; see Appendix A for the precise definition.

### 3.2 Extended gluing and the open/closed Sullivan PROP

For the PROP case, we will need to extend the gluing to the case where one window is active and the second window is inactive. In this case, we glue the surfaces and distinguished points as above and simply delete foliation in the rectangle. This may result in additional windows becoming inactive.

**Remark 3.1.** We do not wish to formalize  $c/o$  PROP structures here. A PROP gluing is given by pairing of all “ins” to all “outs” of two different surfaces and gluing on all of them. In apparent terminology, we can have the open and closed PROP substructures separate or at once. Technically there are also so-called vertical compositions which in our cases are always just disjoint unions. The brane labelling is handled in the same fashion as in the  $c/o$  case. For more details see Appendix A.7.1.

**Proposition 3.2.** *The open/closed Sullivan spaces are closed under the extended gluing, when gluing an open (respectively closed) “in” to an open (respectively closed) “out” window with the same weight or to an empty “out” window.*

**Corollary 3.3.** *This also gives the structure of a  $c/o$ ,  $i/o$  modular operad in the terminology of the appendix. This implies that these spaces form  $c/o$  PROP. These structures also exist in the brane labelled case.*

**Proof.** Both conditions for families in the Sullivan spaces are stable under the gluing. (1) If arcs only run from “in” to “out”, they also do so after gluing an “in” to an “out” window: Indeed a foliation could only run from “in” to “in” on the glued surface if there was a foliation running from “in” to “in” in the surface to whose “in” window we glue. The extended gluing only kills foliations. (2) After gluing all “in” boundaries are active: This is clear if we do not glue to an empty “out”. But even if we glue to an empty “out” this holds true, since in this case only leaves get deleted on the surface to whose “in” we glue. These foliations run to “out” windows of that surface and hence to “out” windows of the glued surface. The “in” windows of the glued surface are unaffected. The number of inactive “out” windows may of course increase.

Since the gluing is associative, we can obtain a  $c/o$  PROP gluing by simply gluing successively as described in the appendix. The first gluing will be a non-self gluing, while all remaining gluings are self-gluings. Since gluing is associative this is insensitive to the order chosen.

The brane labelling is external to the foliation gluing, so the last statement readily follows. ■

There is actually a open/closed colored dg-PROP structure on the chain level, if we use cellular chains as we demonstrate in Section 6. This is induced by a topological quasi-PROP structure on the topological level; see the appendix for the definitions of these types of PROPs.

### 3.3 Discretization of the model $N$ -valued foliations

We wish to point out that the subset of discrete valued foliations is stable under the compositions in both the  $c/o$  structure and the  $c/o$  PROP structure.

#### 3.3.1 Discrete representation for *discretely weighted* $\beta$ -arc families

In order to decorate, we will change the picture slightly. Previously we had arc graphs, whose edges are not allowed to be parallel. For a *discretely weighted*  $\beta$ -arc families with weighting  $wt$  we will consider its *leaf representation* to be the foliation each of whose bands  $e$  has  $wt(e)$  number of leaves. This means that we consider an new type of arc graph which has  $wt(e)$  parallel edges for each underlying edge of the original arc graph. We will call this the *discrete representative* of the arc graph.

## 4 Algebraic $c/o$ structures

Given a  $\beta$ -arc graph with weights that are natural numbers, we are going to associate an operation on the Hochschild complexes  $\text{CH}^*(A_{\mathcal{O}}, M_{B,B'})$  of a fixed Frobenius algebra  $A_{\mathcal{O}}$  with coefficients in a module  $M_{B,B'}$  with  $B, B' \in \mathcal{B}$ . These modules will be given by tensor products

of Frobenius algebras  $A_B$  indexed by elements of  $\mathcal{B}$ :  $M_{B,B'} : A_{B'} \otimes A_B$ . These operations will be defined on the isomorphic double sided bar-complexes  $B(A_B, A_\emptyset, A_{B'})$ . For most operations we will need that  $A_\emptyset$  is commutative, but this is not always the case. We will indicate when the commutativity can be dropped.

## 4.1 Frobenius algebras and systems of Frobenius algebras

### 4.1.1 Notation for Frobenius algebras

The main actors are Frobenius algebras, so we will fix some notation.

Recall that a Frobenius algebra (FA) is a triple  $(A, 1, \langle , \rangle)$  where  $(A, 1)$  is a unital (super-) algebra and  $\langle , \rangle$  is a non-degenerate (super-) symmetric even pairing which satisfies

$$\langle ab, c \rangle = \langle a, bc \rangle.$$

We will set

$$\int a := \langle a, 1 \rangle.$$

Then  $\int$  is cyclically (super-)invariant, i.e. a trace

$$\int abc = \langle ab, c \rangle = \langle c, ab \rangle = \int cab.$$

Since  $\langle , \rangle$  is non-degenerate on  $A$ , so is  $\langle , \rangle_{A \otimes A} := \langle , \rangle \otimes \langle , \rangle \circ \tau_{2,3}$  on  $A^{\otimes 2} \otimes A^{\otimes 2}$ . Here  $\tau_{2,3}$  is the commutativity constraint for the symmetric monoidal category applied to the second and third factors, be it the category of vector spaces, dg-vector spaces or  $\mathbb{Z}/2\mathbb{Z}$  graded vector spaces. In our current setup this just interchanges the second and third factors of  $A \otimes A \otimes A \otimes A$  or in the super case changes these factors and introduces the usual super sign.

We will omit all super signs from our discussion as they can be added in a straightforward fashion.

The multiplication  $\mu : A \otimes A \rightarrow A$  has an adjoint  $\Delta : A \rightarrow A \otimes A$  defined by

$$\langle \Delta a, b \otimes c \rangle_{A \otimes A} = \langle a, bc \rangle. \tag{1}$$

Moreover given a FA we will consider a basis  $\Delta_i$ , set  $g_{ij} = \langle \Delta_i, \Delta_j \rangle$  and let  $g^{ij}$  the coefficients of the inverse of  $(g_{ij})$ , viz. the inverse ‘‘metric’’.

There are two special elements

$$e = \mu \Delta(1) = \sum_{ij} \Delta_i g^{ij} \Delta_j,$$

which we call the Euler element and

$$C = \Delta(1) = \sum \Delta_i g^{ij} \otimes \Delta_j,$$

which we call the Casimir element.

Notice that Euler element commutes with every element.

$$ae = a\mu\Delta(1) = \mu\Delta(a) = \mu\Delta(1)a = ea.$$

This follows by direct computation and the Frobenius relations

$$(\text{id} \otimes \mu)(\Delta \otimes \text{id}) = \Delta\mu = (\mu \otimes \text{id})(\text{id} \otimes \Delta),$$

which in turn follow from the definition of  $\Delta$  and the invariance of the pairing (1).

### 4.1.2 Adjoint maps

Notice that for any map  $r : A \rightarrow B$  between two Frobenius algebras there is an *adjoint map*  $r^\dagger : B \rightarrow A$  defined by

$$\langle r^\dagger(b), a \rangle = \langle b, r(a) \rangle.$$

This is equivalent to

$$\int r^\dagger(b)a = \int br(a). \quad (2)$$

These maps arise in geometric situations as follows. Let  $i : N \rightarrow M$  be the inclusion map, where  $M$  is a compact manifold and  $N$  is a compact submanifold. Then  $i$  induces a map  $i^*$  from  $A := H^*(M)$  to  $B := H^*(N)$ . By Poincaré duality there is a push forward  $i_* : B \rightarrow A$ . In the previous notation if  $r = i^*$  then  $r^\dagger = i_*$ .

**Lemma 4.1.** *In general, we have the Projection Formula*

$$r^\dagger(r(a)b) = ar^\dagger(b).$$

**Proof.**

$$\langle r^\dagger(r(a)b), c \rangle = \langle r(a)b, r(c) \rangle = \langle b, r(ca) \rangle = \langle ar^\dagger(b), c \rangle,$$

where we used the cyclic symmetry of the product twice. ■

With the self-intersection condition Section 4.6 in mind, we define the element

$$e_r^\perp := r(r^\dagger(1)).$$

### 4.1.3 Systems of Frobenius algebras

**Definition 4.2.** A  $\mathcal{B}$ -Frobenius algebra is a set of Frobenius algebras  $A_S$  indexed by  $S \in \mathcal{P}(\mathcal{B})$  together with algebra maps  $r_{S,S'} : A_S \rightarrow A'_{S'}$  whenever  $S \subset S'$ , such that for  $S \subset S' \subset S''$ :  $r_{S',S''} \circ r_{S,S'} = r_{S,S''}$ .

Note that in particular if  $A_\emptyset$  is commutative every  $A_S$  is an  $A_\emptyset$  module via the restriction map. More precisely, every  $A_S$  is a left and a right  $A_\emptyset$  module via the maps  $\lambda(a, a') := r_{\emptyset S}(a)a'$  and  $\rho(a, a') := a'r_{\emptyset S}(a)$ . If  $A_\emptyset$  is not commutative, we still have that  $A_S$  is a left  $A_\emptyset$  module and a right  $A_\emptyset^{\text{op}}$  module.

### 4.1.4 Basic brane label systems

Given a brane label set  $\mathcal{B}$  one set choices of  $\mathcal{B}$ -Frobenius algebras is given by a collection  $A_B$ ,  $B \in \mathcal{B}$  and  $A_\emptyset$  together with maps  $r_B : A_\emptyset \rightarrow A_B$ .

For any  $S \in \mathcal{P}\mathcal{B}$  with  $|S| \geq 2$  we simply set  $A_S = 0$  where we allow the zero algebra to be a Frobenius algebra.

We call these systems basic brane label systems and for simplicity deal only with these. The data of the Frobenius algebras and morphisms will be called a basic  $\mathcal{B}$  Frobenius algebra.

**Remark 4.3.** In the following we will mostly deal with only basic  $\mathcal{B}$  Frobenius algebra in order to not unduly burden the reader with yet more structures that we would need in order to deal with the general case. All the results do however generalize to the general case if we introduce propagators to fix the c/o structure on the algebraic side.

**Notation 4.4.** Given  $A_B$  we will use the notation  $1_B, e_B, \Delta_B^i, \langle, \rangle_B, g_{ij}^B, g_B^{ij}, e_B^\perp, \dots$  for its unit, Euler element, basis  $A_B$ , metric inverse metric,  $e_{r_B}^\perp$  etc.

We will also omit the label  $\emptyset$  i.e. write  $e$  for  $e_\emptyset, A$  for  $A_\emptyset$  if no confusion can arise.

**Definition 4.5.** We say that a basic  $\mathcal{B}$ -FA satisfies the condition of commutativity  $(C)$  if  $A_\emptyset$  is commutative.

And we say that a  $\mathcal{B}$ -FA satisfies the the Euler compatibility condition or the *condition*  $(E)$  if for all  $B \in \mathcal{B}, a^{(1)}, a^{(2)} \in A_B$

$$(E) \quad \sum_{ij} r_B^\dagger(a^{(1)} \Delta_i^B) g_B^{ij} r_B^\dagger(\Delta_i^B a^{(2)}) = e_\emptyset r_B^\dagger(a^{(1)} a^{(2)}).$$

**Definition 4.6.** A basic  $\mathcal{B}$ -Frobenius algebra satisfies the *self-intersection* condition  $(I)$  if for all  $B \in \mathcal{B}$

$$(I_1) \quad r_B r_B^\dagger(a) = a e_B^\perp \quad \text{and} \quad (I_2) \quad e_B e_B^\perp = r_B(e).$$

**Proposition 4.7.** A basic system of  $\mathcal{B}$  Frobenius algebra which satisfies the self-intersection condition  $(I)$  satisfies the Euler condition  $(E)$ .

**Proof.** We will show that the r.h.s. and the l.h.s. of  $(E)$  have the same inner product with any element  $b$  of  $A$ :

For all  $b \in A_\emptyset, a, a' \in A_B$

$$\begin{aligned} \sum_{ij} \int b r_B^\dagger(a \Delta_i^B) g_B^{ij} r_B^\dagger(\Delta_j^B a') &= \sum_{ij} g_B^{ij} \int_B r_B(b) a \Delta_i^B r_B r_B^\dagger(\Delta_j^B a') \\ &\stackrel{(I_1)}{=} \sum_{ij} g_B^{ij} \int_B r_B(b) a \Delta_i^B \Delta_j^B a' e_B^\perp = \int_B r_B(b) a a' e_B e_B^\perp \\ &\stackrel{(I_2)}{=} \int_B r_B(b) a a' r_B(e) = \int b e r_B^\dagger(a a'), \end{aligned}$$

where the first equality follows from equation (2), the third equality from the definition of  $e_B$  and the fact that  $e_B$  as the Euler element commutes with all other elements and the last equality follows from the projection formula and the fact that  $e$  commutes.  $\blacksquare$

#### 4.1.5 Geometric data

One example of the basic data is given by a compact manifold  $M$  together with a collection  $N_B \subset M, B \in \mathcal{B}$  of compact submanifolds. We can then set  $A_B := H^*(N_B)$  and use the restriction maps  $r_B$  given by pullback. These satisfy the first condition  $(I_1)$  of  $(I)$  due to the self-intersection formula where  $e_B^\perp = e(N_{M/N_B})$  is the Euler class of the normal bundle of  $N_B$  in  $M$ . The second condition  $(I_2)$  follows from the excess intersection formula for homology [16] applied to the diagram

$$\begin{array}{ccc} N_B & \xrightarrow{\Delta_B} & N_B \times N_B \\ i_B \downarrow & & i_B \times i_B \downarrow \\ M & \xrightarrow{\Delta} & M \times M \end{array} \quad (3)$$

keeping in mind that  $\mu = \Delta^*, r_B = i_B^*$

$$\begin{aligned} r_B(e) &= r_B \mu^\dagger(1) = i_B^* \Delta^* \Delta_*(1) = \Delta_B^*(i_B^* \times i_B^*) \Delta_*(1) \\ &= e_B^\perp \Delta_B^* \Delta_{B*} i_B^*(1) = e_B^\perp \Delta_B^* \Delta_{B*}(1) = e_B^\perp e_B. \end{aligned}$$

Alternatively one can use decomposition  $TM|_{N_B} = TN_B \oplus N_{M/N_B}$  and multiplicativity of the Euler class.

**Remark 4.8.** We can also formalize the geometricity by staying in the framework of Frobenius algebras, but postulating a new axiom which guarantees the equations one would obtain from excess intersection formulas from all embedding and intersection diagrams analogous to (3).

**Corollary 4.9.** *A basic geometric  $\mathcal{B}$  Frobenius algebra satisfies the Euler condition (E).*

#### 4.1.6 Hochschild complexes

The action on the closed sector is on the Hochschild cochain-complex of  $A$ . Recall that the Hochschild chain complex of an  $A$  bimodule  $M$  is the complex  $\text{CH}_n(A, M)$

$$\text{CH}_n(A, M) = M \otimes A^{\otimes n}$$

and whose differential is given by  $d = \sum_i (-1)^i d_i$ , where the  $d_i$  are the pre-simplicial differentials

$$\begin{aligned} d_0(m \otimes a_1 \otimes \cdots \otimes a_n) &= ma_1 \otimes a_2 \otimes \cdots \otimes a_n, \\ d_i(m \otimes a_1 \otimes \cdots \otimes a_n) &= m \otimes a_1 \otimes \cdots \otimes a_{i-1} \otimes a_i a_{i+1} \otimes a_{i+2} \otimes \cdots \otimes a_n, \\ d_n(m \otimes a_1 \otimes \cdots \otimes a_n) &= a_n m \otimes a_1 \otimes \cdots \otimes a_{n-1}. \end{aligned}$$

There are degeneracies inserting 1 into the  $i$ th position

$$\begin{aligned} s_i : \text{CH}_n(M, A) &\rightarrow \text{CH}_{n+1}(M, A), \\ m \otimes a_1 \otimes \cdots \otimes a_n &\mapsto m \otimes a_1 \otimes \cdots \otimes a_{i-1} \otimes 1 \otimes a_i \otimes \cdots \otimes a_n. \end{aligned}$$

The Hochschild chain complex  $\text{CH}_*(A, M)$  is also sometimes called the cyclic bar complex and is denoted by  $B_*(A, A)$ .

The Hochschild co-chain complex is dually given by

$$\text{CH}^n(A, M) = \text{Hom}(A^{\otimes n}, M)$$

with the dual differential  $d^{\text{CH}^*} = \sum_i (-1)^i d_i^{\text{CH}^*}$ ,  $d^{\text{CH}^*} : \text{CH}^n(A, M) \rightarrow \text{CH}^{n+1}(A, M)$ , where for  $f \in \text{CH}^n(A, M)$

$$\begin{aligned} d_0^{\text{CH}^*} f(a_1 \otimes \cdots \otimes a_{n+1}) &= a_1 f(a_2 \otimes \cdots \otimes a_n), \\ d_i^{\text{CH}^*} f(a_1 \otimes \cdots \otimes a_{n+1}) &= f(a_1 \otimes \cdots \otimes a_{i-1} \otimes a_i a_{i+1} \otimes a_{i+2} \otimes \cdots \otimes a_n), \\ d_{n+1}^{\text{CH}^*} f(a_1 \otimes \cdots \otimes a_{n+1}) &= f(a_1 \otimes \cdots \otimes a_n) a_{n+1}. \end{aligned}$$

The degeneracies dualize to  $s_i^{\text{CH}^*} : \text{CH}^n(A, M) \rightarrow \text{CH}^{n-1}(A, M)$

$$s_i^{\text{CH}^*} f(a_1 \otimes \cdots \otimes a_{n-1}) = f(a_1 \otimes \cdots \otimes a_{i-1} \otimes 1 \otimes a_i \otimes \cdots \otimes a_{n-1}).$$

In case  $M = A$  multiplication of functions gives a natural product

$$\cup : \text{CH}^n(A, A) \otimes \text{CH}^m(A, A) \rightarrow \text{CH}^{n+m}(A, A).$$

Notice that if  $A$  is a Frobenius algebra, it is isomorphic to its dual as a bi-module. Since  $A \simeq \check{A}$ ,  $\text{CH}^n(A, A) \simeq A \otimes \check{A}^{\otimes n} \simeq A^{\otimes n+1} \simeq \text{CH}_n(A, A)$ . The cup product and the product pairing, make  $\text{CH}^\bullet$  into a graded Frobenius algebra. Furthermore, the differentials  $d$  and  $d^{\text{CH}^*}$  dualize to one and another.

### 4.1.7 Reduced Hochschild complex

For technical reasons discussed in [8] it is actually easier to work with the reduced Hochschild co-chain complex  $\overline{\text{CH}}^*(A, A)$ . This complex is the subcomplex of functions that vanish on all degeneracies that is functions  $f : A^{\otimes n} \rightarrow A$  such that  $f(a_1, \dots, 1, \dots, a_n) = 0$  where 1 is plugged in into any position. The complex inherits the differential and computes the same cohomology as the original complex. Dually there is the reduced bar complex  $\overline{\text{CH}}_*(A, A)$  or  $\overline{B}_*(A, A)$  which we shall use in the closed sector.

### 4.1.8 Double sided bar construction

For the open action, we will consider the double sided bar complexes  $B(S, T) := B_\bullet(A_S, A, A_T)$  whose components are defined as

$$B_n(A_S, A, A_T) = A_S \otimes A^{\otimes n} \otimes A_T$$

and whose differential is given by  $d = \sum_i (-1)^i d_i$ , where the  $d_i$  are the pre-simplicial differentials

$$\begin{aligned} d_0(a_S \otimes a_1 \otimes \cdots \otimes a_n \otimes a_T) &= a_S a_1 \otimes a_2 \otimes \cdots \otimes a_n \otimes a_T, \\ d_i(a_S \otimes a_1 \otimes \cdots \otimes a_n \otimes a_T) &= a_S \otimes a_1 \otimes \cdots \otimes a_{i-1} \otimes a_i a_{i+1} \otimes a_{i+2} \otimes \cdots \otimes a_n \otimes a_T, \\ d_n(a_S \otimes a_1 \otimes \cdots \otimes a_n \otimes a_T) &= a_S \otimes a_1 \otimes \cdots \otimes a_n \otimes a_n a_T. \end{aligned}$$

**Remark 4.10.** Notice that since we are dealing with Frobenius algebras, this is isomorphic to  $\text{CH}^\bullet(A, A_T \otimes A_S)$  and again the differentials dualize to one and another.

### 4.1.9 Degeneracies

The double sided complex is actually simplicial, which means that it also has degeneracy maps

$$\begin{aligned} s_i : B_n(A_S, A, A_T) &\rightarrow B_{n+1}(A_S, A, A_T), \\ a_S \otimes a_1 \otimes \cdots \otimes a_n \otimes a_T &\mapsto a_S \otimes a_1 \otimes \cdots \otimes a_{i-1} \otimes 1 \otimes a_i \otimes \cdots \otimes a_n \otimes a_T. \end{aligned}$$

### 4.1.10 Brane labelled bar complexes

Fix a  $\mathcal{B}$  Frobenius algebra. For a window  $w$  on a brane labelled surface with labelling  $\beta$  we set  $B(w) := B(\beta(w))$  if  $w$  is open and  $B(w) = B(\beta(w)) = B(\emptyset, \emptyset) := \overline{\text{CH}}_n(A, A)$  if  $w$  is closed.

## 4.2 Gluing in brane labelled complexes

As we have noted, the complexes  $B(\beta)$  have non-degenerate graded inner products which allows us to dualize them. Using this dualization, we can compose two correlation functions for the basic brane label case. In the general case we would need to introduce propagators to do this. We will refrain from adding this technical point here for clarity of the discussion.

Given (graded) vector spaces  $V_\beta : \beta \in I$  over a ground field  $k$  with an involution  $\bar{\phantom{a}}$  on  $I$ , isomorphisms  $V_\beta \simeq V_{\bar{\beta}}$  s.t.  $\bar{\bar{a}} = a$  and (graded) non-degenerate even symmetric pairings  $\langle \cdot, \cdot \rangle_\beta$  for each  $V_\beta$  let  $C_\beta = \sum \Delta_i^\beta g_\beta^{ij} \otimes \bar{\Delta}_j^\beta$  be the Casimir element for the induced pairing between  $V_\beta$  and  $V_{\bar{\beta}}$  expressed in a basis  $(\Delta_i^\beta)$ .

We can compose two correlators two correlators  $Y : \bigotimes_{l \in L} V_{\beta_l} \rightarrow k$  and  $Y' : \bigotimes_{l' \in L'} V_{\beta_{l'}} \rightarrow k$  where  $L$  and  $L'$  are labelling sets by inserting a Casimir.

More precisely given  $l_0 \in L$  and  $l'_0 \in L'$  such that  $\beta_{l_0} = \bar{\beta}_{l'_0} = \beta$  we define their composition  $Y \circ_{l_0 l'_0} Y' : \bigotimes_{l'' \in (L \setminus \{l_0\} \sqcup L' \setminus \{l'_0\})} V_{\beta_{l''}} \rightarrow k$  by

$$Y \circ_{l_0 l'_0} Y' \left( \bigotimes_{l \in L \setminus \{l_0\}} v_l \otimes \bigotimes_{l' \in L' \setminus \{l'_0\}} v_{l'} \right)$$

$$= \sum_{ij} Y \left( \left( \bigotimes_{l \in L \setminus \{l_0\}} v_l \right) \otimes \Delta_i^\beta \right) g^{ij} Y' \left( \left( \bigotimes_{l' \in L' \setminus \{l'_0\}} v_{l'} \right) \otimes \bar{\Delta}_j^\beta \right),$$

where  $\Delta_i^\beta$  is in the position  $l_0$  and  $\bar{\Delta}_j^\beta$  is in position  $l'_0$ . If  $\beta_{l_0} \neq \bar{\beta}_{l'_0}$  we set the composition to 0. In the more general case these would be non-zero and the composition would use propagators.

Alternatively, we could also dualize the maps  $Y$  using  $C_{\beta_l}$  in any position  $l$  to obtain maps to  $V_{\beta_l}$  instead of  $k$  and then compose these maps. There is an analogous procedure for self-gluing.

**Remark 4.11.** In our case  $I = \mathcal{B} \times \mathcal{B} \cup \{\emptyset, \emptyset\}$ ,  $\overline{(S, T)} = (T, S)$ ,  $V_\beta = B(\beta)$  the corresponding bar complex and the isomorphisms  $\bar{\cdot}: B(S, T) \rightarrow B(T, S)$  are given by

$$a_S \otimes a_1 \otimes \cdots \otimes a_n \otimes a_T \mapsto a_T \otimes a_n \otimes \cdots \otimes a_1 \otimes a_S$$

and  $B(\emptyset, \emptyset) \rightarrow B(\emptyset, \emptyset)$

$$a_0 \otimes \cdots \otimes a_n \mapsto a_0 \otimes a_n \otimes \cdots \otimes a_1.$$

**Remark 4.12.** In order to give a brane labelled c/o structure, we should consider slightly enriched more complicated data. For this we would have to look at tensor products of cyclic tensor products of bar complexes  $B(S_1, S_2) \otimes B(S_2, S_3) \otimes \cdots \otimes B(S_n, S_1)$ . Again in the interest of brevity, we will not introduce this kind of complexity in a formal fashion here.

**Remark 4.13.** There are actually two c/o structures, one can compose the bar complexes or their duals, viz. the correlators. Of course these operations are dual to each other.

## 5 Correlators

### 5.1 A universal formula for correlators

There is a universal formula for the correlators. It is given by partitioning, decorating and decomposing the surface of a discretely weighted arc family along the arcs into little pieces of surface  $S_i$  and integrating around these pieces. We will now give the details.

#### 5.1.1 Decorating the boundary

Fix a basic  $\mathcal{B}$  collection of Frobenius algebras. For each *discretely weighted*  $\beta$ -arc family  $\alpha$ , we will define a map

$$Y(\alpha) := \bigotimes_{w \in \text{Windows of } \alpha} B(\beta(w)) \rightarrow k.$$

These functions are homogeneous and their homogeneous components are zero by definition unless  $a_w \in B_{\alpha(w)-1}(\beta(w))$ .

Given a collection of homogeneous elements we will decorate the pieces belonging to the boundary of the discrete representation of  $\alpha$  by the elements of the bar complexes

$$\begin{aligned} a_w &= a_S^w \otimes a_1^w \otimes \cdots \otimes a_{\alpha(w)-1}^w \otimes a_T^w & \text{if } \beta(w) = (S, T), \\ a_w &= a_0^w \otimes a_1^w \otimes \cdots \otimes a_{\alpha(w)-1}^w & \text{if } \beta(w) = (\emptyset, \emptyset). \end{aligned}$$

Notice that the boundary of the underlying surface minus the discrete representative of the graph is a disjoint union of intervals, which may or may not contain marked points. We call these the *boundary pieces*. There are three types of boundary pieces

- (1) those not containing a marked point,
- (2) those containing a marked point  $\beta$ -labelled by  $\emptyset$ ,
- (3) those containing a marked point with  $\beta$ -label not  $\emptyset$ .

In case (3), if we remove the marked point we will have two components which we will call half sides of the boundary piece. Now each piece of type (1) and the half sides of the pieces of type (3) belong to a unique window. A piece of type (2) comes from a unique closed window/boundary component. Moreover these pieces all come in a natural linear order in each window as do the half sides of a piece of type (3) if we consider the marked point to lie in between the half sides.

We decorate the boundary pieces as follows:

Type	description of $s$	Decoration
(1)	$s$ is the $i$ th piece of type (1) of the window $w$	$a_i^w \in A$
(2)	$s$ is the unique piece of type (2) of the closed window $w$	$a_0^w$
(3)	the marked point of $s$ is labelled by $S$ and the half sides in their order belong to the not necessarily distinct windows $w_1, w_2$	$(a_S^{w_1}, a_S^{w_2})$

### 5.1.2 Weights

Let  $\{S_i : i \in I\}$  be the components of complement of the discrete representative of a given discretely weighted  $\beta$  arc family  $\alpha$ . Each of these pieces has a polygonal boundary, where the sides of the polygons alternate between pieces of the boundary and arcs running between them. If we decorate the surface as described above every second side is a decorated piece of boundary. We will call these the decorated sides.

To each decorated side  $s$  of  $S_i$ , we associate a weight depending  $\omega$  on its type and decoration.

**Table 1.** General weights.

Type	Decoration	Weight $\omega(s)$
(1) $s$ without marked point	$a \in A_\emptyset$	$a$
(2) $s$ with marked point marked by $\emptyset$	$a \in A_\emptyset$	$a$
(3) $s$ marked point marked by $S$	$(a_S^{(1)}, a_S^{(2)}), a_S^i \in A_S$	$r_{\emptyset S}^\dagger(a_S^{(1)} a_S^{(2)})$

### 5.1.3 The formula

Moreover, the  $S_i$  are oriented and so hence are their boundaries. This means that the sides comprising each boundary component come with a cyclic order. If there is only one boundary component for a given  $S_i$ , this gives a cyclic order over which we will integrate the given weights. If there are more components, in which case the underlying arc family is not quasi-filling, then we need to assume (C) in order to make the following expression independent of choices. For a homogeneous  $\mathbf{a} = \bigotimes_{w \in \text{Windows of } \alpha} a_w \in \bigotimes_{w \in \text{Windows of } \alpha} B(\beta(w))$  such that  $a_w \in B_{\alpha(w)-1}(\beta(w))$ , we decorate as above and define

$$Y_{S_i}(\mathbf{a}) = \int e^{-\chi(S)+1} \prod_{\substack{\text{Decorated sides} \\ s \text{ of } S_i}} \omega(s) \prod_{\substack{\text{Punctures } p \\ \text{inside } S_i}} r_{\emptyset \beta(p)}^\dagger(e_{\beta(p)}). \quad (4)$$

If  $\mathbf{a}$  is as above but there is some  $a_w \notin B_{\alpha(w)-1}(\beta(w))$  we set  $Y_{S_i}(\mathbf{a}) = 0$ .

We then define

$$Y_{(\Gamma, w)}(\mathbf{a}) := \prod_i Y_{S_i}(\mathbf{a}) \quad (5)$$

and extend by linearity.

### 5.1.4 Signs

The correlators above actually have hidden signs which come from the permutation of the input variables to their respective position. In the bar complexes these signs can be read off by imposing that the tensor symbols have degree 1. On the geometric side there are signs as well which are fixed by fixing an enumeration of the flags, angles or edges. In general we adhere to the sign conventions spelled out in [8, Section 1.3.4].

## 5.2 Action of the c/o structure of discretely weighted arc-graphs

We say a c/o structure acts via correlation functions if the composition of the elements of the c/o is compatible with the composition of the correlation functions. In short  $Y(\alpha \circ_{w,w'} \alpha') = Y(\alpha) \circ_{w,w'} Y(\alpha')$  where  $\circ_{w,w'}$  denotes the gluing of the window  $w$  and  $w'$  holds as well as the corresponding equation for the self-gluing.

**Theorem 5.1.** *For a basic  $\mathcal{B}$ -Frobenius algebra the c/o structure of discretely weighted arc-graphs acts on the collection of complexes  $B(\beta)$  and the isomorphic Hochschild complexes via the correlation functions  $Y$ .*

Just like there are algebras over operads, we can define algebras over c/o structures. The theorem above reads: The collection of bar complexes  $B(S, T)$  form an algebra over the c/o structure of discretely weighted arc-graphs.

**Proof.** The proof is a case by case study which occupies Section 5.3. ■

## 5.3 Case by case analysis of the discrete arc-graph action

The gluing of the surfaces with discrete arcs breaks down into individual local gluings of pairs of surfaces  $S_i$  and  $S'_j$ . In case the surfaces are distinct, there are five cases of this gluing depicted in Figs. 2 and 3. The cases a) and b) are the ones familiar from the closed gluing [8], the cases c) and d) are new in the open/closed case. The gluing c) appears when we are gluing two open windows where none of them is the only window in its boundary component. The gluing d) appears when gluing two open windows each of which is the only window in its boundary component. The most complicated case is when one of the windows is the only window, while the other is not. This case e) is given in Fig. 3.

### 5.3.1 Non-self gluing, the closed case

In the case that there is no self-gluing: a)–b) correspond to:

$$\left[ \int \dots w \Delta_i^\emptyset w' \dots \right] g_\emptyset^{ij} \left[ \int \dots w'' \Delta_j^\emptyset w''' \dots \right] = \int w' \dots w'' \dots w''', \quad (6)$$

where the  $w$ ,  $w'$ ,  $w''$  are the weights of the adjacent sides and we use Einstein summation conventions. We have also included any factors of  $e$  into the ellipses.

### 5.3.2 Non-self gluing case in the simple brane case

Assuming the simple brane case, all labels have to be the same, say  $S$  then c) corresponds to

$$\begin{aligned} & \left[ \int \dots w r_S^\dagger (a_S \Delta_i^S w' \dots) \right] g_S^{ij} \left[ \int \dots w'' r_S^\dagger (\Delta_j^S a'_S w''' \dots) \right] \\ &= \left[ \int_S r_S(w' \dots w) a_S \Delta_i^S \right] g_S^{ij} \left[ \int_S \Delta_j^S a'_S r_S(w''' \dots w'') \right] \end{aligned}$$

**Figure 2.** Types of local gluings: a) two sides without marked points; b) side with marked point labelled by  $\emptyset$  to side with marked point labelled by  $\emptyset$ ; c) half a labelled side with marked point labelled by  $S$  to half side with marked point labelled by  $T$ ; d) full side with labelled point marked by  $S$  to full side with labelled point marked by  $T$ .

**Figure 3.** e) Gluing of a lone window with an open marked point to window with two marked points.

$$= \int w' \dots wr_S^\dagger(a_S a'_S) w''' \dots w'' = \int \dots wr_S^\dagger(a_S a'_S) w''' \dots w'' w',$$

while d) corresponds to

$$\begin{aligned} & \left[ \int \dots wr_S^\dagger(\Delta_i^S \Delta_k^S) w' \dots \right] g_S^{ij} g_S^{kl} \left[ \int \dots w'' r_S^\dagger(\Delta_l^S \Delta_j^S) w''' \dots \right] \\ & = \int w' \dots wr_S^\dagger(\Delta_i^S g_S^{ij} \Delta_j^S) w''' \dots w'' = \int \dots wr_S^\dagger(e_S) w''' \dots w'' w'. \end{aligned}$$

The case e) has two subcases. 1) there are three surfaces which are glued:

$$\begin{aligned} & \left[ \int \dots wr_S^\dagger(a_S \Delta_i^S) w' \dots \right] g_S^{ij} \left[ \int \dots w'' r_S^\dagger(\Delta_k^S a'_S) w''' \dots \right] g_S^{kl} \left[ \int \dots w^{(vi)} r_S^\dagger(\Delta_j^S \Delta_l^S) w^{(v)} \dots \right] \\ & \times \left[ \int_S a'_S r_S(w''' \dots w'') \Delta_k^S \right] g_S^{kl} \int_S \Delta_l^S r_S(w^{(v)} \dots w^{(vi)}) \Delta_j^S g_S^{ij} \left[ \int_S \Delta_i^S r_S(w' \dots w) a_S \right] \end{aligned}$$

$$= \int_S \dots wr_S^\dagger(a_S a'_S) w''' \dots w'' w^{(v)} \dots w^{(vi)} w',$$

and the case 2) where only two surfaces are glued

$$\begin{aligned} & \left[ \int \dots wr_S^\dagger(a_S \Delta_i^S) w' \dots w'' r_S^\dagger(\Delta_k^S a'_S) w''' \dots \right] g_S^{ij} g_S^{kl} \left[ \int \dots w^{(vi)} r_S^\dagger(\Delta_j^S \Delta_l^S) w^{(v)} \dots \right] \\ &= \left[ g_S^{ij} \int_S a'_S r_S(w''' \dots wr_S^\dagger(a_S \Delta_i^S) w' \dots w'') \Delta_k^S \right] g_S^{kl} \int_S \Delta_l^S r_S(w^{(v)} \dots w^{(vi)}) \Delta_j^S \\ &= g_S^{ij} \int_S a'_S r_S(w''' \dots wr_S^\dagger(a_S \Delta_i^S) w' \dots w'' w^{(v)} \dots w^{(vi)}) \Delta_j^S \\ &= g_S^{ij} \int \dots wr_S^\dagger(a_S \Delta_i^S) w' \dots w'' w^{(v)} \dots w^{(vi)} r_S^\dagger(\Delta_j^S a'_S) w''' \dots \end{aligned}$$

In this case we have to use commutativity (C) and the Euler compatibility (E):

$$\begin{aligned} & g_S^{ij} \int \dots wr_S^\dagger(a_S \Delta_i^S) w' \dots w'' w^{(v)} \dots w^{(vi)} r_S^\dagger(\Delta_j^S a'_S) w''' \dots \\ & \times g_S^{ij} \int \dots w w' \dots w'' w^{(v)} \dots w^{(vi)} r_S^\dagger(a_S \Delta_i^S) r_S^\dagger(\Delta_j^S a'_S) w''' \dots \\ &= \int \dots w w' \dots w'' w^{(v)} \dots w^{(vi)} r_S^\dagger(a_S a'_S) e, \end{aligned}$$

which is the contribution we get from the glued surfaces, since there is one self-gluing involved and this makes the Euler characteristic go up by one.

### 5.3.3 The self gluing cases

So far we have assumed that the two (half) sides that are glued are on different  $S_i$  and  $S'_j$ . It can happen that they belong to the same surface. In these cases, much like in the case e) 2), there are fewer integrals and instead an Euler class factor  $e$  appears. In the case that there is self-gluing: a)–b) correspond to:

$$\left[ g_\emptyset^{ij} \int \dots w \Delta_i^\emptyset w' \dots w'' \Delta_j^\emptyset w''' \dots \right] = \int w' \dots w'' \dots w''' e.$$

This r.h.s. is the contribution to correlator for the glued surface since the self-gluing changes the Euler characteristic by  $-1$ . Again we need to use (C).

The cases c), d) are analogous to the case e) 2). The self gluing decreases the Euler characteristic by one, while the summation gives the factor  $e$  by condition (E). The two cases for e) then either involve only one or two integrals, respectively; correspondingly the gluing then gives rise to a factor of  $e$  or  $e^2$ , respectively.

There is one more local gluing which comes from gluing consecutive windows corresponding to Fig. 1 cases e) and f). In these cases two half sides of a *single* side marked by a point labelled by some  $S \neq \emptyset$  are glued together.

This corresponds to the following equation in the contribution to the correlator of  $S_i$

$$\int \dots wr^\dagger(\Delta_i^S g^{ij} \Delta_j^S) w' \dots = \int \dots wr^\dagger(e_S) w'' \dots$$

When performing the gluing on the whole window, it might happen, that there are also self-gluing for the surfaces  $S_i$  at some other sides, in which case we need (C) and (E) and proceed as above. If there are more consecutive open gluings on one  $S_i$ , we produce two punctures and correspondingly two factors of  $r_S^\dagger(e_S)$ .

**Figure 4.** (g) Gluing consecutive half sides.

## 5.4 Partitioning arc graphs and the action of arc graphs

Given a discrete weighting  $w$  for an arc graph  $(F, \beta, \Gamma)$  or  $\Gamma$  for short we define  $\Gamma(w)$  to be the graph in which the edge  $e$  has been duplicated  $w(e) - 1$  times. This is we replace  $e$  with  $w(e)$  parallel copies of  $e$ .

We define its discretized version  $P\Gamma$  of  $\Gamma$  to be given by the formal sum of the  $\Gamma(w)$

$$P\Gamma = \sum_{w: \text{discrete weighting of } \Gamma} \Gamma(w).$$

### 5.4.1 Action of arc graphs

Given correlation functions  $Y(\Gamma, w)$  for discretely weighted arc graphs  $(\Gamma, w)$  we define

$$Y(\Gamma) := Y_{P\Gamma}$$

by extending  $Y$  as a function to formal sums.

### 5.4.2 Examples: multiplication and comultiplication in the open sector

As an example we will consider the arc graphs given in Fig. 5. This triangle gives a correlation function, which when dualized on the bottom edge yields a multiplication and when dualized on the top two edges yields a comultiplication. A more familiar form is given in the Sullivan case; see Section 6.5.1 below.

Given

$$a = a_T^{(2)} \otimes a_1 \otimes \cdots \otimes a_n \otimes a_S^{(1)} \in B_n(A_T, A, A_S)$$

and

$$a' = a_S^{(2)} \otimes a'_1 \otimes \cdots \otimes a'_m \otimes a_U^{(1)} \in B_m(A_S, A, A_U)$$

their product which lies in  $B_{n+m+1}(A_T, A, A_U)$  is given by

$$m_{TSU}(aa') = a_T^{(2)} \otimes a_1 \otimes \cdots \otimes a_n \otimes r_S^\dagger(a_S^{(1)} a_S^{(2)}) \otimes a'_1 \otimes \cdots \otimes a'_m \otimes a_U^{(1)}.$$

The calculation goes as follows. The integrals are  $\int r_T^\dagger(a_T^{(1)} a_T^{(2)}) = \int_T a_T^{(1)} a_T^{(2)}$  which dualizes to  $\text{id}_T(a_T^{(1)}) = a_T^{(1)}$  and likewise for  $U$ . For the rectangles we get either  $\int a_i a_j''$  or  $\int a_i' a_k''$  which dualize to  $\text{id}(a_i)$  and  $\text{id}(a_j)$ . Finally we get  $\int r_S^\dagger(a_S^{(1)} a_S^{(2)}) a_{n+1}''$  which dualizes to  $r_S^\dagger \circ \mu$ .

The corresponding co-products by dualizing are  $\Delta_{TSU} : B(A_T, A, A_U) \rightarrow B(A_U, A, A_S) \otimes B(A_S, A, A_T)$  let

$$a'' = a_T^{(2)} \otimes a_1'' \otimes \cdots \otimes a_{n+m+1}'' \otimes a_U^{(1)},$$

**Figure 5.** To the left: an arc graph  $\Gamma$  in a triangle yielding the open sector multiplication or the comultiplication. To the right: a discrete summand of  $P\Gamma$  with weights 2 and 3 together with a decoration of it.

$$\Delta_{TSU}(a'') = \sum_i [a_T^{(2)} \otimes a''_1 \otimes \cdots \otimes a''_{i-1} \otimes (r_S(a_i))^{(1)}] \otimes [(r_S(a_j))^{(2)} \otimes a_{i+1} \otimes \cdots \otimes a_n \otimes a_U^{(1)}],$$

where  $\Delta_S(r_S(a_i)) = (r_S(a_i))^{(1)} \otimes (r_C(a_j))^{(2)}$  using Sweedler's notation. For this we dualize  $\int r_S^\dagger(a_S^{(1)} a_S^{(2)}) a''_{n+1} = \int_{S \otimes S} (a_S^{(1)} \otimes a_S^{(2)}) \Delta_S(r_S(a''_i))$ .

## 6 Open/closed string topology

### 6.1 Cell actions

We will now consider chain complexes whose chain groups are generated by generators indexed by arc graphs. The basic way to obtain actions of these chain complexes is to let each generator act via the graph that indexes it as we explain below.

Analogously to the purely closed situation [7, 8] there are two cases which we can study. The open/closed moduli space case and the open/closed Sullivan PROP case. Although their basic underpinnings are the same the details are slightly different, again as in [7, 8]. For the open/closed PROP case, we will have to change the actions of the weighted arc graphs slightly by using degeneracy maps. This is what corresponds to the breaking of the symmetry between “ins” and “outs” in the PROP itself. After putting in these degeneracies, we obtain a dg-PROP action on the cell level. We will give the full details below. The moduli space case is discussed further in Section 7.

### 6.2 The open/closed Sullivan c/o-colored topological quasi-PROP

So far we have only a partial gluing structure. At the expense of having associativity only up to homotopy, we can rectify this partial structure to a full open/closed colored structure (see the Appendix for a definition). Again without being too technical this means that we will have PROP gluings for two given elements  $\alpha \in \widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$  and  $\alpha' \in \widetilde{\mathcal{Sull}}^{c/o}(n_2, n_3, m_3, m_4)$  and a pairing of the closed “out” windows of  $\alpha$  and the “in” windows of  $\alpha$ . Likewise given elements and appropriate pairings there are gluings  $\alpha \in \widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$  and  $\alpha' \in \widetilde{\mathcal{Sull}}^{c/o}(n_3, n_4, m_2, m_3)$  on all the open windows. Or even gluing all “in” to all “out” windows  $\alpha \in \widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$  and  $\alpha' \in \widetilde{\mathcal{Sull}}^{c/o}(n_2, n_3, m_2, m_3)$ .

This will be done by means of a flow. This flow analogous to the flow in [7], but differs from the flow in [11]. The flow in [11] might take us outside the Sullivan spaces.

Given two elements  $\alpha \in \widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$  and  $\alpha' \in \widetilde{\mathcal{Sull}}^{c/o}(n_3, n_4, m_2, m_3)$ , the flow depends on the choice of a pairing of open “in” windows of  $\alpha'$  and “out” windows of  $\alpha$  and scales the weights of all the arcs incident to the  $m_2$  open “in” windows of  $\alpha'$  simultaneously. Given such a pairing the flow at time  $t$  scales each weight of an arc to an “in” window  $w'$  of  $\alpha'$  by the factor of  $1 - t(\alpha(w)/\alpha(w') - 1)$  where  $w$  is the window of  $\alpha$  paired with  $w'$ . At time 1, each window has the weight of its partner under the pairing. Now glue using the previously established gluings on all windows. Since the partial structure was bi-modular, it does not matter in which order the gluings are performed. We can repeat the analogous procedure for open windows or all windows at once. The proof that these gluings are associative up to homotopy, which is the definition of a topological quasi-PROP goes along the same line of arguments as in [7, Section 5.6]:

**Proposition 6.1.** *The open/closed Sullivan spaces  $\widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$  form a (two-colored) brane labelled topological quasi-PROP.*

**Proof.** The two colors are open and closed. We can either choose to glue only these, or glue both open and closed windows at one. The brane labelling is just given by the left and right brane labels of each window. The associativity up to homotopy comes from the fact that we used a flow. Flowing backwards interpolates between the different bracketings. These flow of course is only on the non-deleted arcs, which are the same set in both bracketings. An arc is deleted if it passes through the preimage of the glued windows. This condition is the same for both iterations in the associativity check. ■

Notice that we have rectified the partial structure on the topological level, but we had to pay the price of relaxing associativity. This weaker structure of course induces a strict structure on the homology.

**Corollary 6.2.** *The homology open/closed Sullivan spaces  $\widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$  form a (two-colored) brane labelled PROP.*

The surprising fact is that although there is only the weaker structure on the topological level, there is already a strict structure on the chain level, when using the correct chains. This is the underlying principle of our constructions.

### 6.3 A CW model for $\mathcal{Sull}^{c/o}$

This paragraph is an application of the methods set forth in [7]. We define the following subspaces of  $\widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$  we let  $\mathcal{Sull}^{c/o}_1(n_1, n_2, m_1, m_2)$  be the subspace of all  $\alpha \in \widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$  such that the  $\alpha$  weight of each “in” window is 1.

**Proposition 6.3.**  *$\mathcal{Sull}^{c/o}_1(n_1, n_2, m_1, m_2)$  is a CW complex, is a sub-topological quasi-PROP and is a deformation retract of  $\widetilde{\mathcal{Sull}}^{c/o}(n_1, n_2, m_1, m_2)$ . The dimension  $k$  cells of this complex are indexed by arc graphs of Sullivan type with  $k + 1$  arcs and their attaching maps are given by deleting arcs and identifying this boundary with the cell of lower dimension.*

**Proof.** The fact that this is a deformation retract is shown again by using a flow. This time the flow scales the weights of the arcs incident to an “in” window  $w$  by a factor of  $1 - t(1/\alpha(w) - 1)$ .

Since for a graph of Sullivan type, all the arcs can be enumerated by going along the “in” windows, we see that before taking PMC orbits, the graphs of a given Sullivan type with  $\alpha$  weight on the “in” windows is simply a product of simplices. Now there is no PMC isotropy inside this product of simplices, but under the action sides may become identified. So for each

arc graph  $\Gamma$  of Sullivan type on a brane labelled windowed surface  $F$ , we obtain a cell  $C(\Gamma)$  whose interior  $\dot{C}(\Gamma)$  is given by a product of open simplices  $\dot{\Delta}^k$ :

$$\dot{C}(\Gamma) = \prod_{w \in \{\text{“in” windows of } F\}} \dot{\Delta}^{|\{\text{arcs incident to } w\}|}.$$

The statement about the attaching maps follows directly from the topology in  $\widetilde{\mathcal{S}}ull^{c/o}$ , where we simply delete an arc in the limit where its weight goes to zero. The fact that this is a sub-topological quasi PROP is immediate upon noticing that the property that the  $\alpha$  weight of each “in” window is one is stable under the operation of gluing.

Since the gluing a window with  $n$  arcs to a window with  $m$  arcs produced at most  $n + m - 1$  arcs we see that the gluing maps are indeed cellular and there are induced maps on the cellular level.

It remains to prove that these maps are associative on the nose. This follows in the same way as in [7, Theorem 5.33]. The proof there essentially goes over to the current situation for the closed part. The open part is actually simpler, since we do not have to worry about the condition of “twisted at the boundary”, since we keep the punctures upon gluing. ■

**Theorem 6.4.** *The cellular chains of  $\mathcal{S}ull_1^{c/o}(n_1, n_2, m_1, m_2)$  are an open/closed colored brane labelled PROP cell model for the spaces  $\widetilde{\mathcal{S}}ull^{c/o}(n_1, n_2, m_1, m_2)$ .*

**Proof.** This follows directly from the proposition. ■

**Corollary 6.5.** *There is a open/closed brane labelled PROP structure on the free Abelian group generated by arc graphs of Sullivan type induced by the corresponding structure on the cellular chains of  $\mathcal{S}ull_1^{c/o}$ .*

**Proof.** This is defined simply by the identification of the free Abelian groups of cellular chains which are generated by the  $C(\Gamma)$  and the free Abelian groups generated by the respective graphs. ■

Notice that in this structure when gluing  $\Gamma$  and  $\Gamma'$  we obtain all the graphs that can appear combinatorially by giving arbitrary weights in  $\Gamma$  and  $\Gamma'$  matching on the windows that are glued, with the extra condition that the arcs of the glued graph have the maximal number, i.e. the corresponding cell has the maximum possible dimension.

## 6.4 The open/closed string topology action on brane labelled Hochschild complexes

### 6.4.1 The correlators in the Sullivan case

In the Sullivan graph case, when decorating and calculating the weights, we also distinguish between “in” and “out” boundaries. We will use the correlators  $Y^{i/o}(\Gamma)$  which are obtained from the  $Y((\Gamma, w))$  by using the degeneracies.

Given an discretely weighted arc family of Sullivan type  $(\Gamma, w)$  on a surface  $F$  with “in” and “out” boundary markings. Let

$$\mathbf{a} = \mathbf{a}^{(\text{in})} \otimes \mathbf{a}^{(\text{out})} \in \bigotimes_{w \in \{\text{“in” windows of } \alpha\}} B(\beta(w)) \otimes \bigotimes_{w \in \{\text{“out” windows of } \alpha\}} B(\beta(w)),$$

we define  $\mathbf{sa}$  as  $\mathbf{a}^{(\text{in})} \otimes \mathbf{sa}^{(\text{out})}$  where  $\mathbf{sa}^{(\text{out})}$  is defined as follows:

Let  $\mathbf{a}^{(\text{out})} = \bigotimes a_w$ . On the window  $w$  of the discrete family enumerate all components of  $w \setminus \{\text{endpoints of arcs incident to } w\}$  in the order induced by the orientation of the surface

starting at 0. Let  $n_1 < n_2 \dots n_k$  be the boundary pieces between non-parallel arcs, which are not flags. Then we set

$$sa_w := s_{n_1} s_{n_2} \dots s_{n_k} a_w.$$

Given  $\mathbf{a} \in \mathbf{a}^{(\text{in})} \otimes \mathbf{a}^{(\text{out})}$  we define

$$Y^{i/o}(\mathbf{a}) := Y(\mathbf{sa}).$$

According to this the correlators will again be multilinear maps

$$Y^{i/o}(\alpha) := \bigotimes_{w \in \text{Windows of } \alpha} B(\beta(w)) \rightarrow k,$$

where these functions are homogeneous and their homogeneous components are zero by definition unless  $a_w \in B_{\alpha(w)-1}(\beta(w), A)$ .

### 6.4.2 Decorations in the string topology case

The above procedure is tantamount to changing the decorations as follows:

**Table 2.** Weights for open/closed string topology.

Type	Decoration	Weight $w(s)$
side without marked point		
part of “in” boundary	$a \in A_\emptyset$	$a$
part of “out” boundary and part of a rectangle	$a \in A_\emptyset$	$a$
part of “out” boundary not part of a rectangle	$1 \in A_\emptyset$	1
side with marked point marked by $\emptyset$	$a \in A_\emptyset$	$a$
side with marked point marked by $S$	$(a_S^1, a_S^2), a_S^i \in A_S$	$r_{\emptyset S}^\dagger(a_S^1 a_S^2)$

In [8] we used angle markings to this effect. In that language the table above is the analog of the decorations for the angle markings in the PROP case. The angles correspond exactly to the components of the boundary minus the arcs.

## 6.5 The action

**Theorem 6.6.** *The open/closed  $\beta$  brane labelled open/closed dg-PROP cell model of  $\widetilde{\text{Sull}}^{c/o}$  provided by  $\text{Sull}_1^{c/o}$  acts in a brane labelled open/closed dg-PROP fashion on the brane labelled Hochschild complexes for a  $\beta$ -Frobenius algebra which satisfies the Euler condition (E).*

This has an immediate geometric consequence by using  $\beta$  Frobenius algebras coming from the geometric data of Section 4.1.5. Notice that in this case the bar complex  $B(\emptyset, \emptyset)$  after dualizing computes  $H_*(LM)$  where  $LM$  is the free loop space [6] and the bar complex  $B(b, b')$  after dualizing computes  $H_*(PM, N_b, N_{b'})$  where  $PM(N_b, N_{b'})$  is the space of paths which start in  $N_b$  and end in  $N_{b'}$ .

**Corollary 6.7.** *If  $M$  is a simply connected compact manifold with a given set of  $D$ -branes realized by submanifolds  $N_b : b \in \mathcal{B}$  then there are open closed string topology type operations on  $H_*(LM)$  and the various  $H_*(PM, N_b, N_{b'})$ .*

Here define new operations through the  $E_2$  term of the respective spectral sequence. One actually can do it for the  $E_1$  term; confer [8]. This is what we call string topology type operations. One can ponder if such operations exist in a purely geometric framework and if these coincide with the ones defined here.

**Figure 6.** Gluing with angle labels in [8], in the current terminology the label 0 corresponds to a side without marked point on an “out” boundary that is not part of a rectangle.

**Proof of Theorem 6.6.** There are two things left to prove, the dg-properties and the compatibility of the gluings on both sides of the action. We first show the dg-properties. In the closed case the argument is the same as in [8, Section 4.2.1]. It basically relies on the fact that the co-multiplication and the multiplication are dual to each other. The argument carries over to the open case upon noticing that the only relevant case is the one where we locally consider an arc which has no parallel arc, as otherwise the terms of the differential cancel out. The only new case is when this arc is the only arc in the window. In this case (unlike in the closed case) removing the incident arc will still leave two decorations. In all other cases one of the decorations before removing the arc will be by 1. In this new case there are however two decorations before and after removing the arc due to the new rules of decorating on open windows, and hence the right hand side of the equations (4.7) and (4.8) of [8] still give the correlators on the surface with the arc removed.

The argument that the gluings on the Hochschild side in view of Theorem 5.1 and the geometric side coincide is completely analogous to [8, Theorem 4.4]. There are two steps in the argument. The first is that on the cellular chain side, only the graphs with maximal dimension appear and we have to check that only these appear on the Hochschild side. This is forced by the labelling. This labelling is equivalent to considering the gluing of [8] for angle labelled graphs (see Fig. 6). If does not want to take this detour one can prove this directly by noticing that the degeneracies duplicate edges on gluing. Now with this gluing the number of arcs is always maximal after gluing. On the Hochschild side, this is automatic as the number of “in” variables has to be equal to the number of “out” variables in order to obtain a non-zero gluing. The second step is to check that the actions given by the discretized arcs coincide before and after gluing. This is the content of Theorem 5.1. The surprising new feature is that among the new local gluings coming from the open sector the compatibility holds only if additionally the condition (E) is satisfied. ■

### 6.5.1 Examples multiplication and comultiplication in the open sector in the string topology case

As an example we will consider the arc graphs given in Fig. 5 but now with the Sullivan decoration. Given

$$a = a_T^{(2)} \otimes a_1 \otimes \cdots \otimes a_n \otimes a_S^{(1)} \in B_n(A_T, A, A_S)$$

and

$$a' = a_S^{(2)} \otimes a'_1 \otimes \cdots \otimes a'_m \otimes a_U^{(1)} \in B_m(A_S, A, A_U)$$

their product now lies in  $B_{n+m}(A_T, A, A_U)$  and is given by

$$m_{TSU}(aa') = \left( \int_S a_S^{(1)} a_S^{(2)} \right) a_T^{(2)} \otimes a_1 \otimes \cdots \otimes a_n \otimes a'_1 \otimes \cdots \otimes a'_m \otimes a_U^{(1)}.$$

The calculation goes as follows. The integrals are  $\int r_T^\dagger(a_T^{(1)} a_T^{(2)}) = \int_T a_T^{(1)} a_T^{(2)}$  which dualizes to  $\text{id}_T(a_T^{(1)}) = a_T^{(1)}$  and likewise for  $U$ . For the rectangles we get either  $\int a_i a'_j$  or  $\int a'_i a''_k$  which dualize to  $\text{id}(a_i)$  and  $\text{id}(a_j)$ . Finally we get  $\int r_S^\dagger(a_S^{(1)} a_S^{(2)}) 1 = \int_S a_S^{(1)} a_S^{(2)}$  which gives the factor in front.

The corresponding co-products  $\Delta_{TSU} : B(A_T, A, A_U) \rightarrow B(A_U, A, A_S) \otimes B(A_S, A, A_T)$  are left unchanged.

## 7 Moduli space actions

In the moduli spaces case, there is an associated chain complex indexed by graphs. The difficulties in this case are manifold. First the cells of the chain complex are open cells. As we saw in [7, 8], the way to deal with this is to pass to the associated graded complex and look at the actions induced from the topological level there. Now there are new problems that arise in the open/closed case. While in the purely closed situation, the “forbidden” gluings which on the topological level gave rise to elements outside the moduli space were codimension one, here there are “forbidden” gluings for whole cells. An example is given in Figs. 7 and 8. We can deal with this by restricting the cells to come from an open/closed duality subspaces of moduli space. Also there are problems since we have to deal with internal marked points.

### 7.1 Point clusters

The property of moduli space that only once punctured polygons may appear among the complementary regions is very fragile under gluing. Not even the inclusion of the open and closed sectors into each other is stable with respect to this condition. So we will allow polygons with an arbitrary number of punctures. Using Strebel differentials, we can put a conformal structure on such a piece and have one distinguished point for this polygon. We now choose the geometric interpretation that all the points in the polygon with their brane labels are a cluster of points located at that distinguished point. We can think of these points as labelled “bosons” sitting on top of each other. In this sense they are equivalent to one internal marked point with a multiple brane label. This is very close to the moduli spaces considered in [13].

### 7.2 Open/closed duality

In [11] we saw that the open/closed duality holds on the chain level. This basically means that any element of  $\widetilde{\text{Arc}}$  can be decomposed into a piece which is purely closed and cylinders whose one end is closed. This is simply obtained by cutting on a closed curve parallel to each boundary. If the boundary is already closed there is no need to cut. An example of this is given in Fig. 9. Notice the since we are cutting, we have the free choice of a point on the boundary and hence the pieces are not unique. They are of course unique up to twisting on the boundary, with the one parameter family on the annulus with closed windows, which is equivalent to moving a marked point marked by  $\emptyset$  along the boundary. On the chain level this does however not hold for the whole space and hence we will impose this condition.

**Definition 7.1.** We say that two arc families  $\alpha$  and  $\alpha'$  are in *general position* with respect to the windows  $w$  of  $\alpha$  and  $w'$  of  $\alpha'$  if the number of arcs after the gluing is subadditive.

**Figure 7.** A gluing of two elements of moduli space whose result does not lie in the moduli space. The window  $AB$  is glued to window  $DE$  and the resulting element is not quasi-filling anymore.

A main result of [7] is that elements of open cells of two purely closed quasi-filling arc graphs are not in general position only in codimension one. This was enough to induce an operad structure on the associated graded of the chains.

Now, we also have problems with gluings of the type where two flags of a window belong to the same complementary region, e.g. the case e) 2) discussed in Section 5.3.3.

**Definition 7.2.** We say an open window of an arc family  $\alpha$  is *degenerate* if its flags are both part of the boundary of a complementary region, but are not an edge of this boundary. The latter can only happen if there is only one marked point on the boundary. This case will be non-degenerate.

An *arc family is non-degenerate* if it has no degenerate windows.

### 7.2.1 Cell complexes

For a  $\beta$  arc graph  $\alpha$  on  $F$ , we let  $C(\alpha)$  be the set of all projective weightings on  $\alpha$ . Recall that a weighting is by positive reals, so that this set is just the open inside of a cell.

The space  $\text{Arc}(F, \beta)(n, m) := \widehat{\text{Arc}}(F, \beta)(n, m) / \mathbb{R}_{>0}$  has decomposition into these open cells

$$\text{Arc}(F, \beta) := \sqcup_{\Gamma: \beta \text{ arc graph on } F \text{ with only active windows}} \dot{C}(\alpha).$$

**Figure 8.** Gluing of two cells of moduli space whose result does not lie in the moduli space. The gluing is along the windows  $ST$  which face each other. Again the result is not quasi-filling.

**Figure 9.** Open/closed duality: cut on the dotted lines.

This gives a complex whose generators are the open cells and whose boundary is given by the differential in the associated CW complex. The terms in the sum are only over those graphs which appear in the boundary. These are the subgraphs with one fewer edge.

**Definition 7.3.** The open/closed duality moduli space is the space given by those arc families which satisfy the following conditions

1. The complementary regions are only polygons possibly with punctures of any finite number.
2. The arc family admits a decomposition under the open/closed duality as above such that
  - (a) the pieces are in general position with respect to the boundaries obtained by cutting and
  - (b) the annuli appearing in the decomposition are non-degenerate.

In particular we let  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s,\beta}$  be the component where the arc families are on  $(F_{g,n}^s, \beta)$  where the point clusters are given by the sets of marked points of cardinality  $s_i$  and  $s = \sum s_i$ , where a point cluster is the set of marked points within one polygonal complementary region.

Notice that the spaces  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s,\beta}$  are stratified by the spaces  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s_1\dots s_k,\beta}$  and each space  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s_1\dots s_k,\beta}$  is a finite unramified cover of  $\mathcal{M}_{g,\delta_1,\dots,\delta_n}^k$ .

To avoid yet additional notation, we will think of  $\mathcal{M}_{g,\delta_1,\dots,\delta_n}^s$  and  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s,\beta}$  as a subspace of  $\text{Arc}(F, \beta)(n_1, n_2)$  where  $n_1$  is the number of  $\delta_i = 1$  and  $n_1 + n_2 = n$  and  $F = F_{g,n}^s$ .

The subspaces are then just given by the disjoint union of open cells of those graphs that satisfy the additional requirements.

There are gluings on the topological level, which are giving by scalings. Given  $\alpha$  and a window  $w$  of it together with  $\alpha'$  and a window  $w'$  on it, we scale all arcs  $\alpha$  by  $\alpha'(w')$  and all arcs of  $\alpha'$  by  $\alpha(w)$ , just as in [12]. After the scaling the two windows have the same weight and we can glue. The structure we get is a two colored operad (open/closed) with the additional information of brane labels. We call such a structure a brane labelled open/closed operad.

**Lemma 7.4.** *This gluing yields a brane-labelled open/closed operad structure. And this induces an operad structure on the complex of open cells.*

**Proof.** On the topological level the only thing that is left to be checked is the associativity. Adapting [12] this is straightforward. For the chains, we notice that the set obtained from composing cells is a union of cells and proceed as in [7]. ■

If we only stick to basic brane labels, we would need to introduce more colors, which would be as usual pairs  $(S, T)$  of  $S, T \neq \emptyset$  or  $(\emptyset, \emptyset)$ .

**Lemma 7.5.** *The open cell complexes of  $\text{Arc}(F, \beta)(n_1, n_2)$  are graded by dimension – which for  $\dot{C}(\Gamma)$  is the number of arcs minus one – and the induced operad structure respects the corresponding filtration and hence passes to the associated graded complexes.*

**Proof.** This follows from the fact that when gluing two windows with  $k$  and  $l$  arcs, the maximal number is  $k + l + 1$ . ■

**Proposition 7.6.** *The associated graded of the complexes of open cells  ${}^{c/o}\mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s,\beta}$  form a sub-operad of the associated graded of the complexes of open cells of  $\text{Arc}(F, \beta)(n_1, n_2)$ .*

**Proof.** We have to show that when gluing two open cells which are in the open/closed moduli part, we are still in the open/closed moduli part up to codimension one. For the closed part this is contained in [7] up to handling the punctures. But since we allow arbitrary punctures in polygons, we do not have to keep track of them. This generalizes directly to gluing on two closed windows in the possible presence of additional open windows. Now we use the condition of the open/closed moduli space to decompose any given two elements into cylinders and pieces that only have closed boundaries. We now only have to consider gluing on such a cylinder along an open window to an open window. Since the cylinder will have a non-degenerate quasi-filling arc family, we see that indeed the result of the gluing will be quasi-filling and non-degenerate as we will locally never glue polygons twice on sides that are not consecutive. ■

To each such cell  $\dot{C}(\Gamma)$  we can associate the correlation function  $Y(\Gamma)$  acting on the appropriate Hochschild co-chains or bar complexes. Now since we passed to the associated graded on the moduli space side, we will have to do the same thing on the algebraic side. This is accomplished by grading with respect to the number of comultiplications, analogous to [8] and then passing to the associated graded. The resulting objects can naturally be called a  $\beta$ -labelled Hom operad.

**Theorem 7.7.** *There is an operadic cell model associated to the  $\beta$ -brane labelled open/closed moduli spaces  $c/o \mathcal{M}_{g,\delta_1,\dots,\delta_n}^{s,\beta}$  which acts on  $\beta$ -labelled Hochschild co-chains via operadic correlation functions with values in a  $\beta$ -labelled Hom operad.*

**Remark 7.8.** On the image this operation is dg with respect to the induced differential.

## 8 Outlook

Again like in [9, 10] we can consider the stabilization. We see that in this case, we need that all the Frobenius algebras  $A_S$  are (normalized) semi-simple in order to pass to the appropriate stabilization.

One case where this would be true would be in Landau–Ginzburg models. We are currently working on the details of this theory.

One can furthermore ask about the modular operad structure on the moduli space. Then further technical complications arise from the intricate structure of the flows defining the chain level structure of the c/o structure in [11]. In this case we will show that there is an underlying solution to the quantum master equation.

## A Appendix: operadic, PROPic and c/o structures

### A.1 The definition of a c/o structure

Specify an object  $\mathcal{O}(S, T)$  in some fixed symmetric monoidal category for each pair  $S$  and  $T$  of finite sets. A  $G$ -coloring on  $\mathcal{O}(S, T)$  is the further specification of an object  $G$  in this category and a morphism  $\mu : S \sqcup T \rightarrow \text{Hom}(\mathcal{O}(S, T), G)$ , and we shall let  $\mathcal{O}_\mu(S, T)$  denote this pair of data.

A  $G$ -colored “closed/open” or *c/o structure* is a collection of such objects  $\mathcal{O}(S, T)$  for each pair of finite sets  $S, T$  together with a choice of weighting  $\mu$  for each object supporting the following four operations which are morphisms in the category:

*Closed gluing:*  $\forall s \in S, \forall s' \in S'$  with  $\mu(s) = \mu'(s')$ ,

$$\circ_{s,s'} : \mathcal{O}_\mu(S, T) \otimes \mathcal{O}_{\mu'}(S', T') \rightarrow \mathcal{O}_{\mu''}(S \sqcup S' - \{s, s'\}, T \sqcup T');$$

*Closed self-gluing:*  $\forall s, s' \in S$  with  $\mu(s) = \mu(s')$  and  $s \neq s'$ ,

$$\circ^{s,s'} : \mathcal{O}_\mu(S, T) \rightarrow \mathcal{O}_{\mu''}(S - \{s, s'\}, T);$$

*Open gluing:*  $\forall t \in T, \forall t' \in T'$  with  $\mu(t) = \mu'(t')$ ,

$$\bullet_{t,t'} : \mathcal{O}_\mu(S, T) \otimes \mathcal{O}_{\mu'}(S', T') \rightarrow \mathcal{O}_{\mu''}(S \sqcup S', T \sqcup T' - \{t, t'\});$$

*Open self-gluing:*  $\forall t, t' \in T$  with  $\mu(t) = \mu(t')$  and  $t \neq t'$ ,

$$\bullet^{t,t'} : \mathcal{O}_\mu(S, T) \rightarrow \mathcal{O}_{\mu''}(S, T - \{t, t'\}).$$

In each case, the coloring  $\mu''$  is induced in the target in the natural way by restriction, and we assume that  $S \sqcup S' \sqcup T \sqcup T' - \{s, s', t, t'\} \neq \emptyset$ .

The axioms are that the operations are equivariant for bijections of sets and for bijections of pairs of sets, and the collection of all operations taken together satisfy associativity.

Notice that we use the formalism of operads indexed by finite sets rather than by natural numbers as in [14] for instance.

## A.2 Restrictions

A c/o structure specializes to standard algebraic objects in the following several ways.

There are the two restrictions  $(\mathcal{O}_\mu(S, \emptyset), \circ_{s, s'})$  and  $(\mathcal{O}_\mu(\emptyset, T), \bullet_{\tau, \tau'})$  each of which forms a  $G$ -colored cyclic operad in the usual sense.

The spaces  $(\mathcal{O}_\mu(S, T), \circ_{s, s'}, \bullet_{\tau, \tau'})$  with only the non self-gluing as structure maps form a cyclic  $G \times \mathbb{Z}/2\mathbb{Z}$ -colored operad, where the  $\mathbb{Z}/2\mathbb{Z}$  accounts for open and closed, e.g., the windows labeled by  $S$  are regarded as colored by 0 and the windows labeled by  $T$  are regarded as colored by 1.

If the underlying category has a coproduct (e.g., disjoint union for sets and topological spaces, direct sum for Abelian groups and linear spaces), which we denote by  $\coprod$ , then the indexing sets can be regarded as providing a grading: i.e.,  $(\coprod_T \mathcal{O}_\mu(S, T), \circ_{s, s'})$  form a cyclic  $G$ -colored operad graded by the sets  $T$ , and  $(\coprod_S \mathcal{O}_\mu(S, T), \bullet_{\tau, \tau'})$  form a cyclic  $G$ -colored operad graded by the sets  $S$ .

## A.3 Modular properties

There is a relationship between c/o structures and modular operads. Recall that in a modular operad there is an additional grading on the objects, which is additive for gluing and increases by one for self-gluing. Imposing this type of grading here, we define a  $(g, \chi - 1)$  c/o structure to be a c/o structure with two gradings  $(g, \chi)$ ,

$$\mathcal{O}_\mu(S, T) = \coprod_{g \geq 0, \chi \leq 0} \mathcal{O}_\mu(S, T; g, \chi)$$

such that

- (1)  $\mathcal{O}_\mu(S, T; \chi - 1) = \coprod_{g \geq 0} \mathcal{O}_\mu(S, T; g, \chi)$  is additive in  $\chi - 1$  for  $\bullet_{t, t'}$ , and  $\chi - 1$  increases by one for  $\bullet^{t, t'}$ ; and
- (2)  $\mathcal{O}_\mu(S, T; g) = \coprod_{\chi \leq 0} \mathcal{O}_\mu(S, T; g, \chi)$  is additive in  $g$  for  $\circ_{s, s'}$ , and  $g$  increases by one for  $\circ^{s, s'}$ .

It follows that a  $(g, \chi - 1)$  c/o structure is a modular  $G$ -colored bi-operad in the sense that the  $\mathcal{O}_\mu(S, T; g)$  form a  $T$ -graded  $\mathbb{R}_{>0}$ -colored modular operad<sup>1</sup> for the gluings  $\circ_{s, s'}$  and  $\circ^{s, s'}$ , and the  $\mathcal{O}_\mu(S, T; 1 - \chi)$  form an  $S$ -graded  $\mathbb{R}_{>0}$ -colored modular operad\* for the gluings  $\bullet_{t, t'}$  and  $\bullet^{t, t'}$ .

## A.4 Brane-labeled c/o structures

A brane-labeled c/o structure is a c/o structure  $\{\mathcal{O}_\mu(S, T)\}$  together with a fixed Abelian monoid  $\mathcal{P}$  of brane labels and for each  $\alpha \in \mathcal{O}_\mu(S, T)$  a bijection  $N_\alpha : T \rightarrow T$  and a bijection  $(\lambda_\alpha, \rho_\alpha) : T \rightarrow \mathcal{P} \times \mathcal{P}$ , such that

- (1)  $\rho(t) = \lambda(N(t))$ ,

<sup>1</sup>We impose neither  $3g - 3 + |S| > 0$  nor  $3(-\chi + 1) + |T| - 3 \geq 0$ .

(2) if  $N_\alpha(t) \neq t$  and  $N_{\alpha'}(t') \neq t'$

$$\begin{aligned} N_{\alpha \bullet_{t,t'} \alpha'}(N_\alpha^{-1}(t)) &= N_{\alpha'}(t'), & N_{\alpha \bullet_{t,t'} \alpha'}(N_{\alpha'}^{-1}(t')) &= N_\alpha(t), \\ \rho_{\alpha \bullet_{t,t'} \alpha'}(N_\alpha^{-1}(t)) &= \lambda_{\alpha'}(t) \rho_{\alpha'}(t'), & \lambda_{\alpha \bullet_{t,t'} \alpha'}(N_\alpha(t)) &= \lambda_{\alpha'}(t') \rho_\alpha(t), \end{aligned}$$

(3)  $N_\alpha(t) \neq t$  and  $N_{\alpha'}(t') \neq t'$

$$\begin{aligned} N_{\bullet_{t,t'}(\alpha)}(N_\alpha^{-1}(t)) &= N_\alpha(t'), & N_{\bullet_{t,t'}(\alpha)}(N_\alpha^{-1}(t')) &= N_\alpha(t), \\ \rho_{\alpha \bullet_{t,t'} \alpha'}(N_\alpha^{-1}(t)) &= \lambda_\alpha(t) \rho_\alpha(t'), & \lambda_{\alpha \bullet_{t,t'} \alpha'}(N_\alpha(t)) &= \lambda_\alpha(t') \rho_\alpha(t), \end{aligned}$$

(4) if either  $N_\alpha(t) = t$  or  $N_{\alpha'}(t') = t'$  but not both, then in the above formulas, one should substitute  $N_{\alpha'}(t')$  for  $N_\alpha(t)$  in the first case and inversely in the second case. (If both  $N_\alpha(t) = t$  and  $N_{\alpha'}(t') = t'$ , then there is no equation.)

This is the axiomatization of the geometry given by open windows with endpoints labeled by right ( $\rho$ ) and left ( $\lambda$ ) brane labels, their order and orientation along the boundary components induced by the orientation of the surface, and the behaviour of this data under gluing.

For a brane-labeled c/o structure and an idempotent submonoid  $\mathcal{B} \subset \mathcal{P}$  (i.e., for all  $b \in \mathcal{B}$ ,  $b^2 = b$ ), one has the  $\mathcal{B} \times \mathcal{B}$ -colored substructures defined by restricting the gluings  $\bullet_{t,t'}$  and  $\bullet^{t,t'}$  to compatible colors  $\lambda(t) = \rho(t')$ .

## A.5 PROPs and partial modular operads

Recall that a PROP is a collection of objects  $\mathcal{O}(S, T)$  as above with two sets of operations. Composition: for each bijection  $T \leftrightarrow S'$  a morphism  $\circ_\phi : \mathcal{O}(S, T) \otimes \mathcal{O}(S', T') \rightarrow \mathcal{O}(S, T')$ . We can think of  $S$  as “in” labels and  $T$  as “out” labels. Mergers or vertical compositions:  $\mathcal{O}(S, T) \otimes \mathcal{O}(S', T') \rightarrow \mathcal{O}(S \amalg S', T \amalg T')$  satisfying the obvious compatibilities, associativities and invariance under bijections.

A partial modular operad is a modular operad in which not all gluing operations need to be defined, when they are defined all the relations hold. A particular kind of partial modular operad is a colored modular operad. There is an additional coloring of  $S$  by some set  $C$  and only like colors can be glued. Another partial structure is the following: For each element in  $\mathcal{O}(S)$  fix a partition of  $S$  into  $S_0 \amalg S_1$ . We can think of  $S_0$  as “in” and  $S_1$  as “out”. The gluings are given for  $\circ_{s,s'} : \mathcal{O}(S) \otimes \mathcal{O}(S') \rightarrow \mathcal{O}(S \setminus \{s\} \amalg S' \setminus \{s'\})$  for all  $s \in S_1$ ,  $s' \in S'_0$ . We will call this an i/o modular operad.

Notice and i/o modular operad in a category with a direct sum induces a PROP.

Given a bijection  $\phi : T \rightarrow S'$  we perform the concatenation of all operations  $\circ_{t,\phi(t)}$ , where the first gluing is a non-self gluing and all further gluings are self-gluings. The mergers are then just defined as the coproduct, which is the disjoint union.

## A.6 Two colored or open/closed colored PROPs

A two colored or open/closed PROP is a PROP with a partition for each the sets  $S, T$  that is given by objects  $\mathcal{O}(S_o \amalg S_c, T_o \amalg T_c)$  and there are gluing operations for bijections  $S_o \leftrightarrow T'_o$  and  $S_c \leftrightarrow T'_c$  that give PROP structures separately (treating the other set as a grading) and jointly.

## A.7 Weaker structures on the topological level

A topological quasi-PROP has the data of PROP but the associativity only needs to hold up to homotopy. Notice that this is enough to guarantee that there is a PROP structure on the

homology level. The adjective “quasi” in any context means that the associativity need not hold and the specification “topological quasi” means that the objects are topological spaces and the associativity holds up to homotopy.

### A.7.1 C/o versions, c/o PROP

To get the  $c/o$  versions, we need two additional colorings on top of all the other structures. This first is open/closed and the second is a coloring  $\mu$  by  $\mathbb{R}$ . The gluing then is partial or colored with respect to both the coloring open/closed and the coloring  $\mu$ .

Thus a  $c/o$  PROP has colors “closed” and “open” together with a real weight on each “in” and each “out”. There will be two types of full gluings: closed and open given by bijections between the open “ins” and “outs” or the closed “ins” and “outs”. The gluings are possible if the bijection  $\phi$  has the property that the weight of  $t$  is the weight of  $\phi(t)$ . Both gluings and the simultaneous open/closed gluing will satisfy the usual equations.

Adding brane labels is straightforward as above.

## Acknowledgments

This project was completed in many phases over the last couple of years. We wish to thank the institutes at which we worked on it for their hospitality and support. These are the MPI, IHES where this work was conceived, and the CTQM in Aarhus where many of the final details were fixed. We also wish to thank Bob Penner and Jørgen Andersen for discussions. Special thanks goes to the organizers of the conference ISQS 2009 which provided the forum to present these ideas and prompted me to finish the project and write up the results.

We also gratefully acknowledge support from the NSF grant DMS-080588.
